**Patient** 

#### INTRODUCTION

- Sickle hemoglobin (HbS) under conditions of deoxygenation polymerizes to cause sickling of red blood cells (RBCs). Oxygenated HbS does not polymerize; thus, increasing oxygen affinity to HbS is a therapeutic strategy for sickle cell disease (SCD).<sup>1</sup>
- Voxelotor (GBT440) is a first-in-class, small molecule that increases the affinity of hemoglobin for oxygen, inhibits polymerization, and reduces sickling, with a subsequent increase in the half-life of RBCs.<sup>2,3</sup>
- In the phase 3 HOPE trial, the use of voxelotor in patients with SCD caused a significant reduction in markers of hemolysis and anemia. We hypothesized that, given this mechanism of action, we would observe improvements in RBC physiology in patients receiving voxelotor.<sup>2</sup>
- In this study, an ektacytometer laser optical rotational red cell analyzer (Lorrca; RR Mechatronics, NL) was used to analyze deformability of RBCs using a defined value of shear stress with an increasing osmotic gradient (Osmoscan) as well as a newer technology to subject these cells to gradual deoxygenation (Oxygenscan). Lorrca and Hemox Analyzer (TCS Scientific Corp.) informed the understanding of RBC physiology in children receiving voxelotor.<sup>4,5</sup>

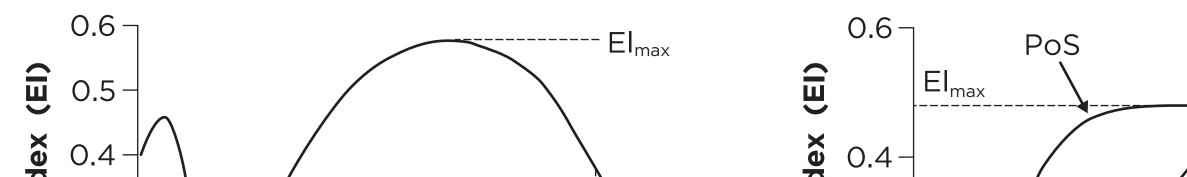

### STUDY DESIGN

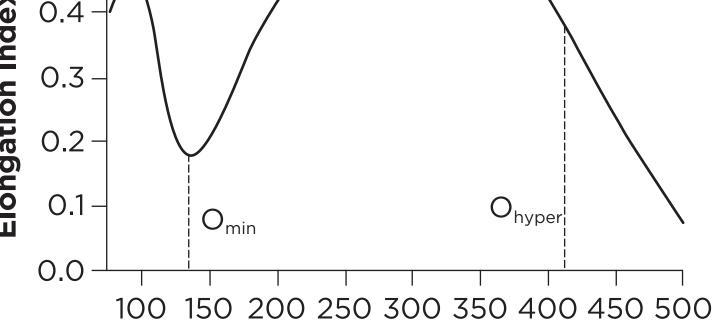

- This pilot study was conducted at Emory University/Children's Healthcare of Atlanta as an investigator-initiated ancillary study to the institutional review board-approved GBT440-007 clinical trial, which evaluated multiple doses of voxelotor at equivalent exposure to adults as 1500 mg/day, based on body weight (NCT02850406).
- Samples from children aged 4 to 11 with SCD (HbSS) who received voxelotor were analyzed before and 12 weeks after starting therapy.
- All participants continued their stable, optimal hydroxyurea dose during treatment with voxelotor.

## **METHODS**

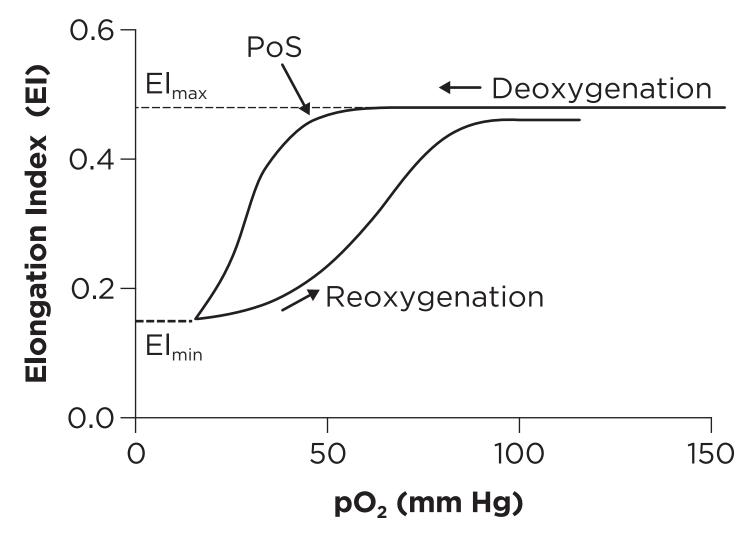

- Blood collected in K2/EDTA was suspended in polyvinylpyrrolidone buffer for analysis. Deformability of RBCs in Osmoscan (Figure 1A) was performed at a shear stress of 30 Pa and varying osmolality gradients (0-600 mOsm/kg). Oxygenscan (Figure 1B) was similarly performed under controlled deoxygenation using nitrogen.
- Evaluated parameters were<sup>5-7</sup>:
- $O_{min}$ : value of the hypotonic osmolality, where 50% of the cells hemolyze in a classic osmotic fragility assay; provides information on the initial surface area to volume ratio.
- **El<sub>max</sub>**: maximal deformability or elongation index; informs RBC cytoskeletal mechanics.
- $O_{hyper}$ : osmolality corresponding to 50% of the  $El_{max}$ ; provides information regarding the cytoplasmic viscosity (MCHC).
- **PoS**: point of sickling, or point on the curve during deoxygenation when sickling begins.
- **El<sub>min</sub>**: corresponds to when sickle RBCs can least elongate.
- Oxygen dissociation curves were obtained using a HemOx Analyzer, and complete blood count parameters were determined on a clinical laboratory hematology analyzer (ADVIA, Siemens). Data were analyzed with Prism using a paired t test.

Table 3. Significant Improvements in Ektacytometry, p50, and p20 Were Observed Under Shear Stress and Deoxygenation

|                                | n  | Pre-treatment<br>(mean ± SEM) | Week 12<br>(mean ± SEM) | P value |
|--------------------------------|----|-------------------------------|-------------------------|---------|
| EI <sub>max</sub> (Osmoscan)   | 10 | 0.49 ± 0.02                   | 0.51 ± 0.01             | 0.0147  |
| O <sub>hyper</sub> (Osmoscan)  | 10 | 412.7 ± 2.5                   | 398.6 ± 5.5             | 0.0052  |
| O <sub>min</sub> (Osmoscan)    | 10 | 112.6 ± 1.9                   | 101 ± 2.6               | 0.0321  |
| PoS (Oxygenscan)               | 10 | 44.1 ± 2.2                    | 30.1 ± 2.0              | 0.0001  |
| El <sub>min</sub> (Oxygenscan) | 10 | 0.19 ± 0.02                   | 0.28 ± 0.03             | 0.0079  |
| El <sub>max</sub> (Oxygenscan) | 10 | 0.49 ± 0.03                   | 0.52 ± 0.02             | 0.0347  |
| p50                            | 9  | 32.8 ± 0.9                    | 24.1 ± 1.4              | 0.0011  |
| p20                            | 9  | 17.2 ± 0.7                    | 9.0 ± 0.9               | 0.0001  |

<sup>a</sup>36-week data are not presented, as most curves closely overlaid with 12-week data. <sup>b</sup>Data for change in Hb affinity with voxelotor for Patient 2 are not available. c36-week data for Patients 8 and 9 are not available.

Figure 3. Osmoscan, Oxygenscan, and p50 Curves at Baseline, Week 12, and Week 36

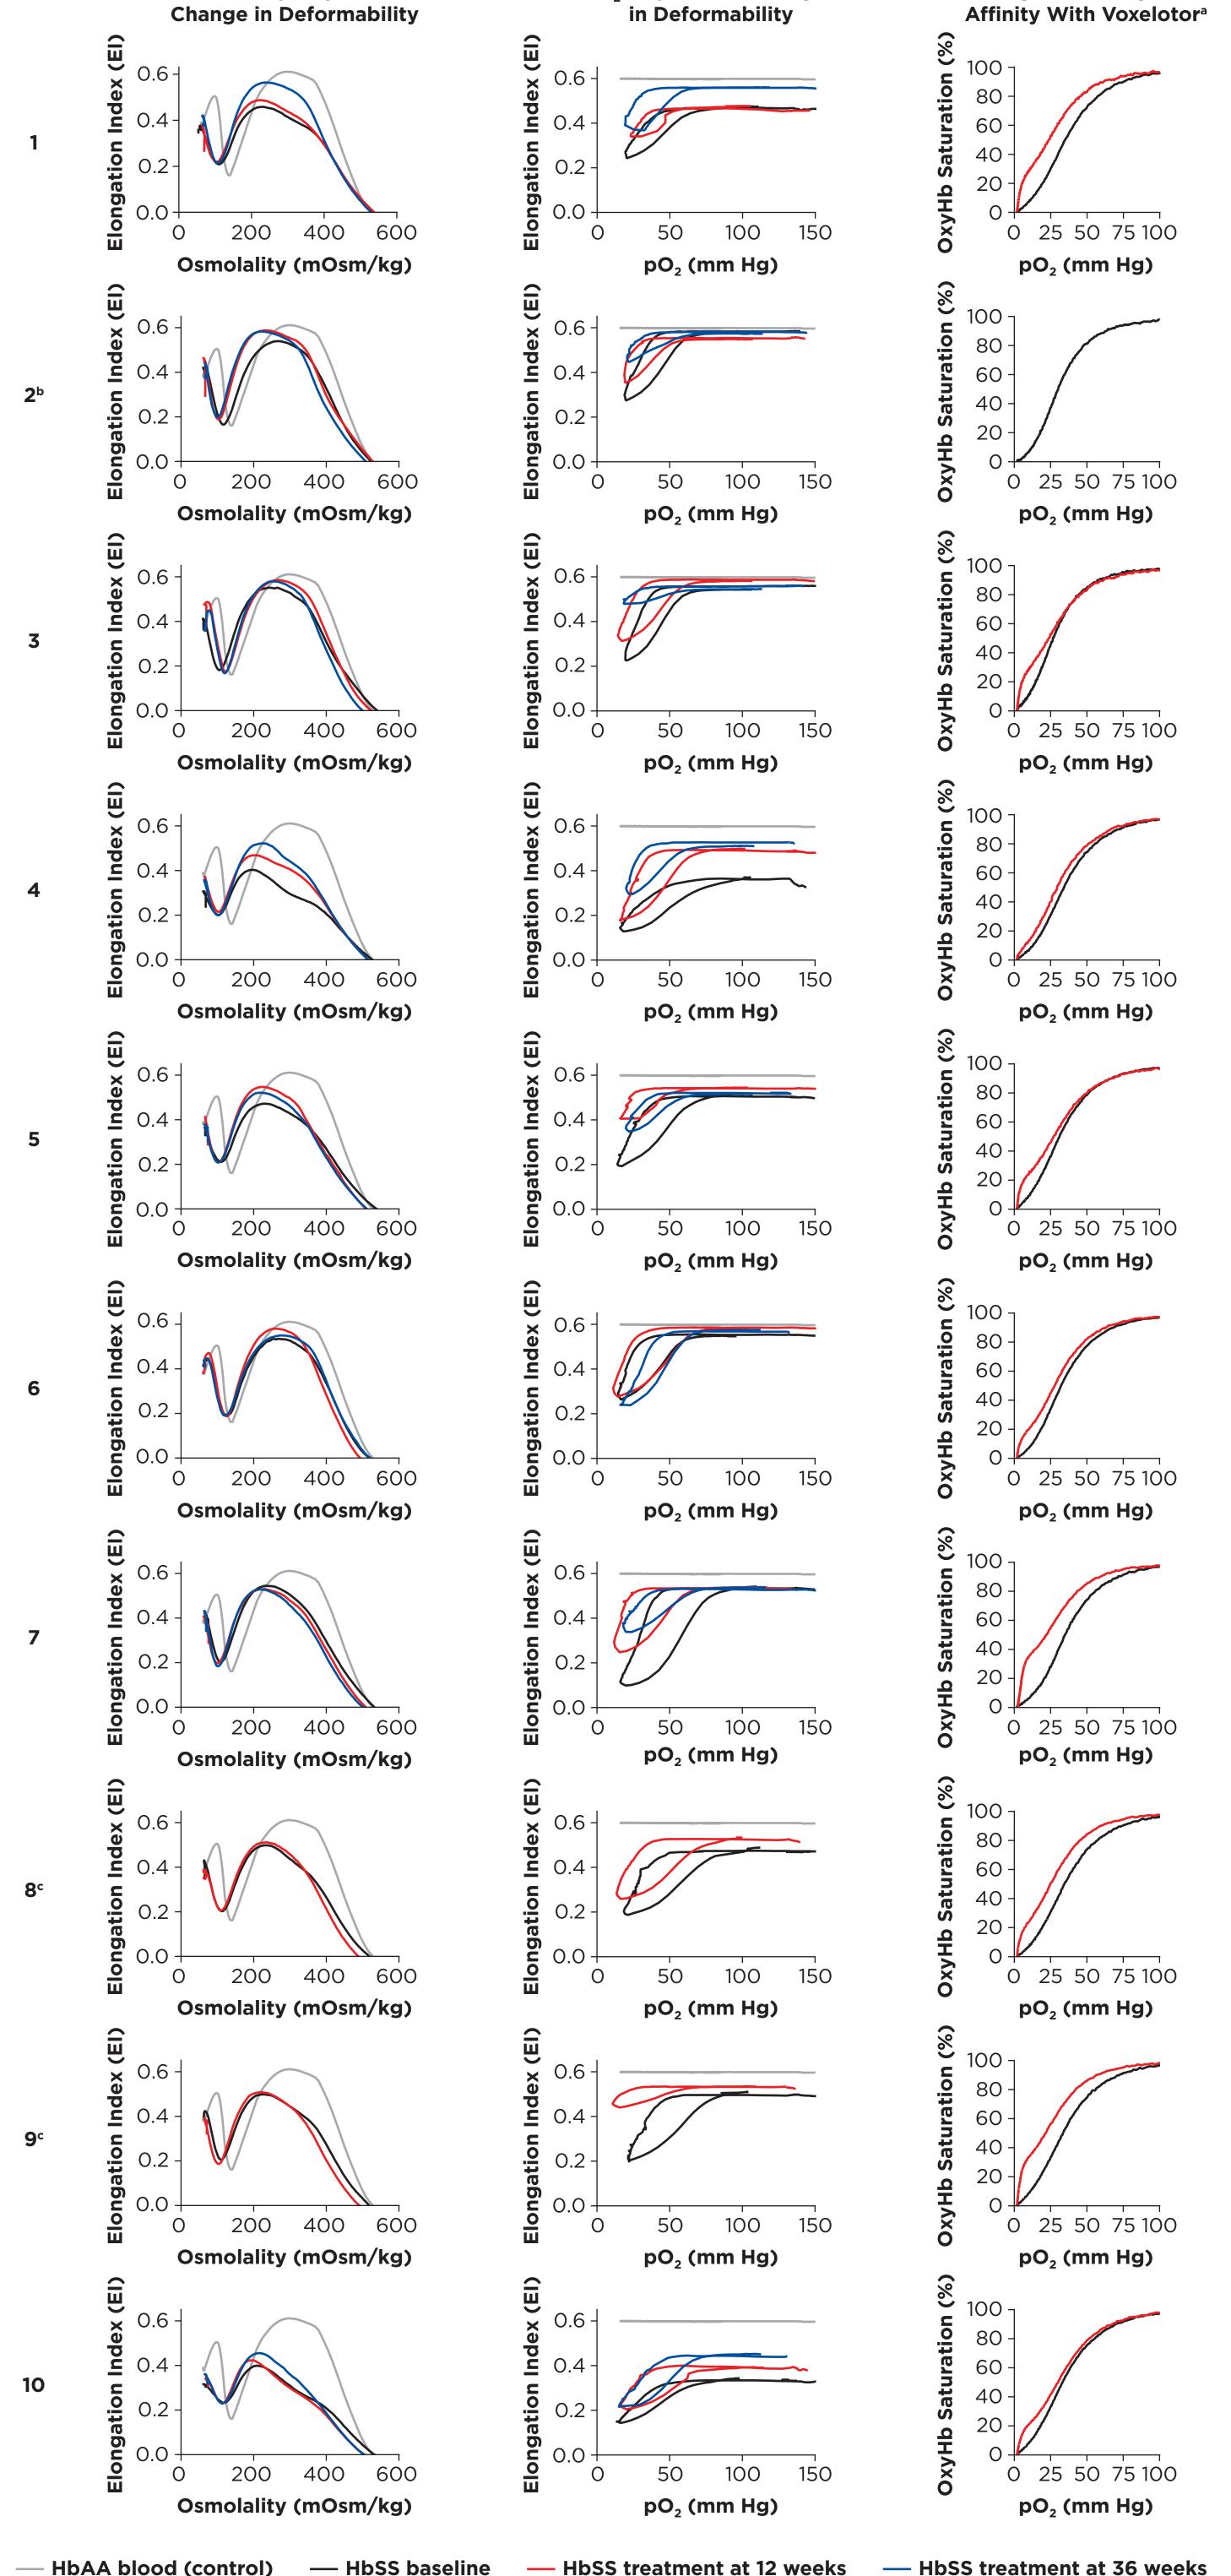

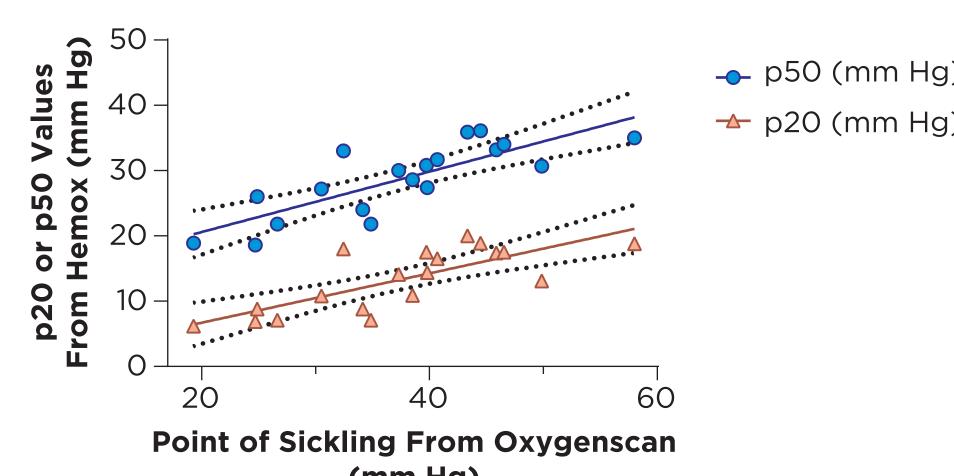

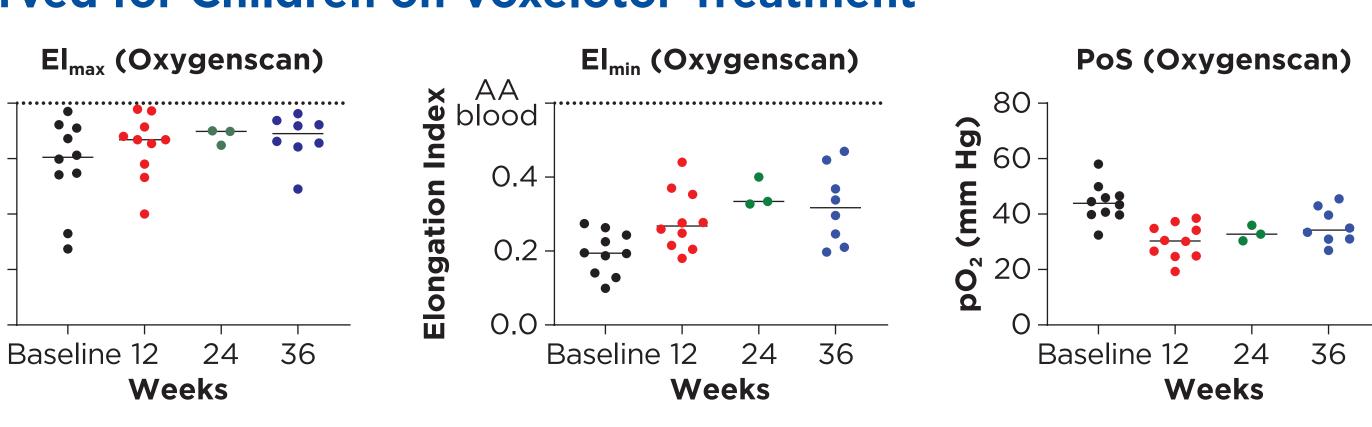

Figure 4. Point of Sickling Decreases as the Hb-O<sub>2</sub> Affinity Increases

- The Oxygenscan curve indicates that deformability of SS RBCs is dependent on the oxygen tension.
- The above correlations (n=19,  $R^2$ =0.65 and 0.59 for p50 and p20, respectively) show that as the  $Hb-O_2$  affinity increases, the PoS decreases (**Figure 4**).
- Previously, we have shown that the p20 decreases as the RBC concentration of
- voxelotor increases in blood from patients taking voxelotor. 1,8 • Therefore, as the RBC concentration of voxelotor increases, we expect the PoS to

decrease and the deformability of RBCs under low oxygen tensions to improve.

#### Figure 5. Sustained Improvements in RBC Deformability Were **Observed for Children on Voxelotor Treatment**

• For children on voxelotor, there was an improvement in RBC deformability in the Oxygenscan as captured by an increase in El<sub>max</sub> and El<sub>min</sub> and a decrease in the PoS (**Figure 5**).

## SUMMARY

- This is the first time that the effect of voxelotor therapy in children aged 4 to 11 has been reported, and shows marked improvements in anemia and hemolysis after 12 and 24 weeks of treatment.
- In this small cohort of children with HbSS, there was:
- Improved RBC deformability, suggested by an increase in  $EI_{max}$  in Osmoscan.
- Improvements in El<sub>max</sub> and El<sub>min</sub> with a decrease in PoS during deoxygenation in Oxygenscan, which theoretically supports voxelotor's ability to inhibit HbS polymerization, improve RBC deformability, and subsequently reduce sickling and hemolysis.
- This study is currently ongoing with periodic clinical and laboratory analyses collected at various time points for longitudinal data.
